**THE BUNNY POOP PROJECT**
The Use of Rabbit Fecal Matter for Lignin Degradation in Wastewater Treatment Systems

**Student:** Smith Pittman  
**Mentors:** Dr. Michelle Young and Dr. Bruce Rittmann

### RESEARCH QUESTION
Lignin is very difficult to break down (1) and is generally discarded as waste (2). Does the predigestion of lignin by a microbial enrichment improve valuable product recovery and reduce the amount of solids from anaerobic digesters at wastewater facilities?

The microbes present in rabbit fecal matter were used, as rabbits eat foods with high concentrations of lignin. Lignin is present in solids, like toilet paper (4). These solids are measured by a metric called Total Solids (TS).

Meaning, the conversion of Volatile Fatty Acids (VFAs) to Methane, used for energy production (3).

These reactors break down biosolids by exposing the waste to complex microbial communities (5).

### METHODS

**There are 4 reactors:**

1. **Fermentative (Ferm)** Functions as pretreatment for the plant matter.
2. **Anaerobic Digestor (AD)** Functions as a control.
3. **Anaerobic Digestor + Ferment (AD+F)** Tests the effectiveness of the pretreated plant matter.
4. **Anaerobic Digestor + Plant (AD+P)** Determines if the pretreatment causes a significant difference.

### RESULTS

**Reactor pH**

<table>
<thead>
<tr>

</tbody>
</table>

**Reactor VFA Production**

**VFA Type**

- Formate
- Acetate
- Propionate
- Isobutyrate
- Butyrate
- Isovalerate
- Valerate
- Isocaproate
- Caproate
- Haptanoate

### CONCLUSION

The addition of pretreated plant matter to an AD reactor maintained pH more efficiently, increased the methane production, decreased the TS output, and increased the conversion of VFAs to methane.
